Let  $f(x) = e^x$ . Let  $P_n(x)$  be the *n*th order Taylor polynomial for f(x) at  $x_0 = 0$ .

- 1. For n = 0, 1, 2, 3, 4
  - (a) Find  $P_n(x)$
  - (b) Check how well P<sub>n</sub>(x) approximates f(x) by graphing P<sub>n</sub>(x) and f(x) on the same set of axes. *Remember:* In Maple, we type in exp(x) rather than e<sup>x</sup>.

Be aware,  $P_3(x)$  is so close that to be able to see, you need to get to a domain of [.49, .51]!

2. Use  $P_3(x)$  to find an approximation for  $e^{1/2}$ ,  $e^2$ . Will these be larger or smaller than the actual value of  $e^{1/2}$ and  $e^2$ ? From the graphs, do they look like good or bad approximations?

Sklensky

Let  $f(x) = \sin(x)$  and let  $P_5(x)$  be the 5th order Taylor polynomial for f(x) at  $x_0 = \pi$ .

1. Find  $P_5(x)$ 

- 2. Verify your answer by graphing  $P_5(x)$  and f(x) on the same set of axes.
- 3. Use P<sub>5</sub>(x) to find an approximation for sin(4) and for sin(6). Will these be larger or smaller than the actual value of sin(6)? How good approximations are they?
